Assignment 1

Loading The Libraries

Loading Input files

```
spam_data <- read.xlsx("spambase.xlsx", sheetName = "spambase_data")
spam_data$Spam <- as.factor(spam_data$Spam)

tecator_data <- read.xlsx("tecator.xlsx", sheetName = "data")
```

1.1 Import the data into R and divide it into training and test sets (50%/50%) by using the following code

```
set.seed(12345)

n = NROW(spam_data)
id = sample(1:n, floor(n*0.5))
train = spam_data[id,]
test = spam_data[-id,]
```

1.2 Use logistic regression (functions glm(), predict()) to classify the training and test data by the classification principles

```
min.model = glm(Spam ~ 1, family=binomial, data=train)
biggest <- formula(glm(Spam ~., family=binomial, data=train))

full.model <- glm(Spam ~., family=binomial, data=train)
step.model <- step(min.model, direction='forward', scope=biggest)
summary(step.model)
```

Manual Feature Selection

```
best_model <- glm(formula = Spam ~ Word35 + Word46 + Word42 + Word44 + Word33 +
  Word45 + Word39 + Word48 + Word30 + Word43 + Word37 +
  Word36 + Word31, family = binomial, data = train)

#export_summs(step.model, best_model,
#model.names = c("Model using Step", "Model Manually Tunned"))
```

Prediction for probability greater than 50% and 90%

```
# prediction
train$prediction_prob <- predict(best_model, newdata = train, type = "response")
test$prediction_prob <- predict(best_model, newdata = test, type = "response")

train$prediction_class_50 <- ifelse(train$prediction_prob > 0.50, 1, 0)
test$prediction_class_50 <- ifelse(test$prediction_prob > 0.50, 1, 0)

train$prediction_class_90 <- ifelse(train$prediction_prob > 0.90, 1, 0)
test$prediction_class_90 <- ifelse(test$prediction_prob > 0.90, 1, 0)
```

Assessing the Model

```
# plots
ggplot(train, aes(prediction_prob, color = Spam)) +
  geom_density(size = 1) + ggtitle("Training Set's Predicted Score for 50% cutoff") +
  scale_color_economist(name = "data", labels = c("negative", "positive")) +
  theme_economist()
```

```
ggplot(test, aes(prediction_prob, color = Spam)) +
  geom_density(size = 1) + ggtitle("Test Set's Predicted Score for 50% cutoff") +
  scale_color_economist(name = "data", labels = c("negative", "positive")) +
  theme_economist()
```

1.2 Assessing the Fit on train dataset for 50%

```
#confusion table
conf_train <- table(train$Spam, train$prediction_class_50)
names(dimnames(conf_train)) <- c("Actual Train", "Predicted Train")
confusionMatrix(conf_train)
```

```

##
##          'Positive' Class : 0
##
```

Analysis: Distribution of the prediction score grouped by known outcome given that our model's final objective is to classify new instances into one of two categories (spam vs. non-spam). We will want the model to give high scores to positive instances (1: spam) and low scores (0 : not spam) otherwise. Ideally you want the distribution of scores to be separated, with the score of the negative instances to be on the left and the score of the positive instance to be on the right.

From the confusion matrix it is apparent that Accuracy on train and test dataset when cutoff=50% is about 83%.

1.3 Assessing the Fit on train dataset for 90%

```
#confusion table
conf_train1 <- table(train$Spam, train$prediction_class_90)
names(dimnames(conf_train1)) <- c("Actual Train", "Predicted Train")
```

```
conf_train1
```

```
##           Predicted Train
## Actual Train    0
##           0 945
##           1 425
```

```
conf_test1 <- table(test$Spam, test$prediction_class_90)
names(dimnames(conf_test1)) <- c("Actual Test", "Predicted Test")
conf_test1
```

```
##           Predicted Test
## Actual Test    0
##           0 937
##           1 433
```

Analysis: Strange, the model only predicts one class!! We know that the prediction of a logistic regression model is a probability, thus in order to use it as a classifier, we'll have to choose a cutoff value, or threshold (cutoff). Where scores above this value will be classified as positive, those below as negative. Let's find this optimum value.

Choosing the best cutoff for test

```
cutoffs <- seq(from = 0.05, to = 0.95, by = 0.05)
accuracy <- NULL

for (i in seq_along(cutoffs)){
  prediction <- ifelse(test$prediction_prob >= cutoffs[i], 1, 0) #Predicting for cut-off

  accuracy <- c(accuracy, length(which(test$Spam == prediction))/length(prediction)*100)}

cutoff_data <- as.data.frame(cbind(cutoffs, accuracy))

ggplot(data = cutoff_data, aes(x = cutoffs, y = accuracy)) +
  geom_line() +
  ggtitle("Cutoff vs. Accuracy for Test Dataset")
```

Cutoff vs. Accuracy for Test Dataset

Analysis: Our small detour suggests that the cutoff value of 50% was the best for our purpose and going higher than this leads to worse results, at 0.8 and above the accuracy drastically reduces which is what we see when we make cutoff as 0.9.

From the confusion matrix it is evident that the model becomes a trivial model(predicts all cases as one class) and thus the prediction is no better than tossing a coin. This should be the absolutely the worst case that we should avoid.

1.4 Use standard classifier `knn()` with $K=30$ from package `kkn`, report the the misclassification rates for the training and test data and compare the results with step 1.2.

```
knn_model30 <- train.kknn(Spam ~ Word35 + Word46 + Word42 + Word44 + Word33 +
  Word45 + Word39 + Word48 + Word30 + Word43 + Word37 +
  Word36 + Word31, data = train, kmax = 30)

train$knn_prediction_class <- predict(knn_model30, train)
test$knn_prediction_class <- predict(knn_model30, test)

conf_train2 <- table(train$Spam, train$knn_prediction_class)
names(dimnames(conf_train2)) <- c("Actual Train", "Predicted Train")
confusionMatrix(conf_train2)

## Confusion Matrix and Statistics
##
```

```

##          Predicted Train
## Actual Train   0    1
##           0 869  76

##

```

Analysis: Using KNN with $K = 30$, increased our training accuracy to 90%, however using training error/accuracy is a bad 83%

1.5 Repeat step 4 for $K=1$ and compare the results with step 4. What effect does the decrease of K lead to and why?

```
knn_model1 <- train.kknn(Spam ~ Word35 + Word46 + Word42 + Word44 + Word33 +  
  Word45 + Word39 + Word48 + Word30 + Word43 + Word37 +  
  Word36 + Word31, data = train, kmax = 1)
```

```
train$knn_prediction_class <- predict(knn_model1, train)  
test$knn_prediction_class <- predict(knn_model1, test)
```

```
conf_train2 <- table(train$Spam, train$knn_prediction_class)  
names(dimnames(conf_train2)) <- c("Actual Train", "Predicted Train")  
confusionMatrix(conf_train2)
```

```
## Confusion Matrix and Statistics

```

Analysis:

Assignment 2 Feature selection by cross-validation in a linear model

2.1 Implement an R function that performs feature selection (best subset selection) in linear regression by using k-fold cross-validation without using any specialized function like `lm()` (use only basic R functions)

```
subset_function <- function(X,Y,N){

X = swiss[,1:5]
Y = swiss[,6:6]
N = 5

df <- cbind(X,Y)

  temp <- NULL
  for(i in 1:NCOL(X)){
    combs <- as.data.frame(gtools::combinations(NCOL(X), r=i, v=colnames(X), repeats.allowed=FALSE))
    combs <- tidyr::unite(combs, "formula", sep = "+")
    temp <- rbind(combs, temp)
  }

  set.seed(12345)
  df2 <- df[sample(nrow(df)),]
  df2$k_fold <- sample(N, size = nrow(df), replace = TRUE)

  result <- NULL
```

```

for (j in 1:NROW(temp))
{
  for(i in 1:N){

train = df2[df2$k_fold != i,]
test = df2[df2$k_fold == i,]

model_forumla = paste("Y ~ ", temp[j,], sep = "")

model <- lm(formula = model_forumla, data = train)
predicted <- predict(model, newdata = test)

RMSE <- sqrt(mean((predicted - test$Y)^2))
data <- cbind(i,temp[j,], RMSE)
result <- rbind(data, result)

}
}

result <- as.data.frame(result)

colnames(result) <- c("kfold", "variables", "rmse")

result$rmse <- as.numeric(result$rmse)
result$no_variables <- nchar(as.character(result$variables))
- nchar(gsub('\\+', "", result$variables)) + 1

variable_performance <- result %>%
  group_by(kfold, no_variables) %>%
  summarise(RMSE = mean(rmse, na.rm = TRUE))

myplot <- ggplot(data = variable_performance, aes(x = no_variables, y = RMSE, color=kfold)) +
  geom_line() + ggtitle("Plot of RMSE vs. Number of variables by folds")

myplot2 <- ggplot(data = result, aes(x = variables, y = rmse, color=kfold)) +
  geom_bar(stat="identity") + ggtitle("Plot of RMSE vs. Features by folds") + coord_flip()

return(list(myplot, myplot2))
}

```

2.2 Test your function on data set swiss available in the standard R repository:

```

subset_function(X = swiss[,1:5], Y = swiss[,6], N = 5)

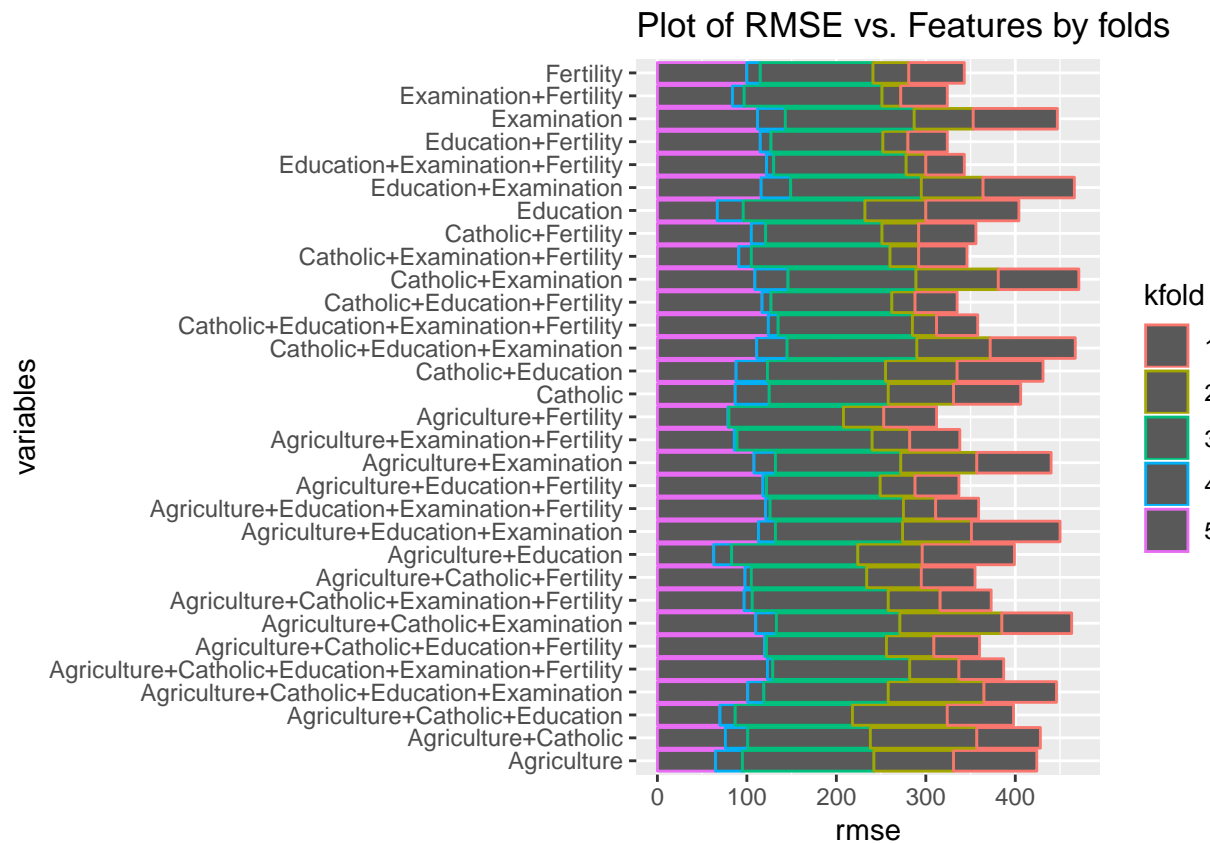

## [[1]]

```

Plot of RMSE vs. Number of variables by folds

```
##  
## [[2]]
```

Analysis:

Assignment 3 Linear regression and regularization

3.1 Import data to R and create a plot of Moisture versus Protein. Do you think that these data are described well by linear model.

```
ggplot(data = tecator_data, aes(x = Protein, y = Moisture)) +
  geom_point() +
  geom_smooth() +
  ggtitle("Plot of Moisture vs. Protein")
```

```
## `geom_smooth()` using method = 'loess' and formula 'y ~ x'
```

Plot of Moisture vs. Protein

Analysis: The data seems fairly linear in nature however there are many outliers. As we can see that data is fairly distributed around the line drawn (above and below) thus there is little bias.

3.2 Multiple Models of varying degree.

#Creating Protein function (increasing degree)

```
final_data <- tecator_data
```

```
final_data$Protein_2_power <- (final_data$Protein)^2
```

```
final_data$Protein_3_power <- (final_data$Protein)^3
```

```
final_data$Protein_4_power <- (final_data$Protein)^4
```

```
final_data$Protein_5_power <- (final_data$Protein)^5
```

```
final_data$Protein_6_power <- (final_data$Protein)^6
```

Analysis:

3.3 Validation of the Model

```
set.seed(12345)
```

```
n = NROW(final_data)
```

```
id = sample(1:n, floor(n*0.5))
```

```
train = final_data[id,]
```

```

test = final_data[-id,]

# model building
M_1 <- lm(data = train, Moisture~Protein)
M_2 <- lm(data = train, Moisture~Protein+Protein_2_power)
M_3 <- lm(data = train, Moisture~Protein+Protein_2_power+Protein_3_power)
M_4 <- lm(data = train, Moisture~Protein+Protein_2_power+Protein_3_power+
          Protein_4_power)
M_5 <- lm(data = train, Moisture~Protein+Protein_2_power+Protein_3_power+
          Protein_4_power+Protein_5_power)
M_6 <- lm(data = train, Moisture~Protein+Protein_2_power+Protein_3_power+
          Protein_4_power+Protein_5_power+Protein_6_power)

train$type <- "train"
test$type <- "test"

final_data <- rbind(test, train)

# predicting new values
M_1_predicted <- predict(M_1, newdata = final_data)
M_2_predicted <- predict(M_2, newdata = final_data)
M_3_predicted <- predict(M_3, newdata = final_data)
M_4_predicted <- predict(M_4, newdata = final_data)
M_5_predicted <- predict(M_5, newdata = final_data)
M_6_predicted <- predict(M_6, newdata = final_data)

# calculating the MSE
final_data$M_1_error <- (final_data$Moisture - M_1_predicted)^2
final_data$M_2_error <- (final_data$Moisture - M_2_predicted)^2
final_data$M_3_error <- (final_data$Moisture - M_3_predicted)^2
final_data$M_4_error <- (final_data$Moisture - M_4_predicted)^2
final_data$M_5_error <- (final_data$Moisture - M_5_predicted)^2
final_data$M_6_error <- (final_data$Moisture - M_6_predicted)^2

# Chaining like Chainsaw
final_error_data <- final_data %>% select(type, M_1_error, M_2_error, M_3_error,
                                         M_4_error, M_5_error, M_6_error) %>%
  gather(variable, value, -type) %>%
  separate(variable, c("model", "power", "error"), "_") %>%
  group_by(type, power) %>%
  summarise(MSE = mean(value, na.rm=TRUE))

ggplot(final_error_data, aes(x = power, y = MSE, color=type)) + geom_point() +
  ggtitle("Mean squared error vs. model complexitiy by dataset type")

```

Analysis: As evident from the plot above, we see that as we increase the model complexity (higher powers of the 'protein'), the training error reduces however the model becomes too biased towards the training set (overfits) and misses the test datasets prediction by larger margins in higher powers.

The best model is M1, that is Moisture-Protein as evident from the least test error (MSE).

The above is a classical case of bias-variance trade-off, which is as follows, as one makes the model fit the training dataset better the model becomes more biased and its ability to handle variation to new dataset decreases (variance), thus one should also maintain a good trade off between these two.

3.4 Perform variable selection of a linear model in which Fat is response and Channel1:Channel100 are predicted by using stepAIC.

```
min.model1 = lm(Fat ~ 1, data=tecator_data[, -1])
biggest1 <- formula(lm(Fat ~ ., data=tecator_data[, -1]))

full.model1 <- lm(Fat ~ ., data=tecator_data[, -1])
step.model1 <- stepAIC(min.model1, direction = 'forward', scope=biggest1)
```

```
summary(step.model1)
```

```
##
## Call:
## lm(formula = Fat ~ Moisture + Protein + Channel100 + Channel141 +
##      Channel17 + Channel48 + Channel142 + Channel150 + Channel145 +
##      Channel166 + Channel156 + Channel190 + Channel160 + Channel170 +
##      Channel167 + Channel159 + Channel165 + Channel158 + Channel144 +
```

```
##      Channel18 + Channel78 + Channel84 + Channel62 + Channel53 +
##      Channel75 + Channel57 + Channel63 + Channel24 + Channel37,
##      data = tecator_data[, -1])
##
